

# Network Security

## Chapter 4

### Asymmetric Cryptography

*“However, prior exposure to discrete mathematics will help the reader to appreciate the concepts presented here.”*

E. Amoroso in another context [Amo94] :o)

## Asymmetric Cryptography (1)

- General idea:
  - Use two different keys  $-K$  and  $+K$  for encryption and decryption
  - Given a random ciphertext  $c = E(+K, m)$  and  $+K$  it should be infeasible to compute  $m = D(-K, c) = D(-K, E(+K, m))$ 
    - This implies that it should be infeasible to compute  $-K$  when given  $+K$
  - The key  $-K$  is only known to one entity  $A$  and is called  $A$ 's *private key*  $-K_A$
  - The key  $+K$  can be publicly announced and is called  $A$ 's *public key*  $+K_A$
- Applications:
  - Encryption:
    - If  $B$  encrypts a message with  $A$ 's public key  $+K_A$ , he can be sure that only  $A$  can decrypt it using  $-K_A$
  - Signing:
    - If  $A$  encrypts a message with his own private key  $-K_A$ , everyone can verify this signature by decrypting it with  $A$ 's public key  $+K_A$
  - Attention: It is crucial, that everyone can verify that he really knows  $A$ 's public key and not the key of an adversary!

- Design of asymmetric cryptosystems:
  - Difficulty: Find an algorithm and a method to construct two keys  $-K, +K$  such that it is not possible to decipher  $E(+K, m)$  with the knowledge of  $+K$
  - Constraints:
    - The key length should be “manageable”
    - Encrypted messages should not be arbitrarily longer than unencrypted messages (we would tolerate a small constant factor)
    - Encryption and decryption should not consume too much resources (time, memory)
  - Basic idea: Take a problem in the area of mathematics / computer science, that is *hard* to solve when knowing only  $+K$ , but *easy* to solve when knowing  $-K$ 
    - Knapsack problems: basis of first working algorithms, which were unfortunately almost all proven to be insecure
    - Factorization problem: basis of the RSA algorithm
    - Discrete logarithm problem: basis of Diffie-Hellman and ElGamal

- Definitions:
  - Let  $\mathbb{Z}$  be the number of integers, and  $a, b, n \in \mathbb{Z}$
  - We say  $a$  divides  $b$  (“ $a \mid b$ ”) if there exists an integer  $k \in \mathbb{Z}$  such that  $a \times k = b$
  - We say  $a$  is *prime* if it is positive and the only divisors of  $a$  are 1 and  $a$
  - We say  $r$  is the *remainder* of  $a$  divided by  $n$  if  $r = a - \lfloor a/n \rfloor \times n$  where  $\lfloor x \rfloor$  denotes the largest integer less than or equal to  $x$ 
    - Example: 4 is the remainder of 11 divided by 7 as  $4 = 11 - \lfloor 11/7 \rfloor \times 7$
    - We can write this in another way:  $a = q \times n + r$  with  $q = \lfloor a/n \rfloor$
  - For the remainder  $r$  of the division of  $a$  by  $n$  we write  $a \text{ MOD } n$
  - We say  $b$  is *congruent*  $a \text{ mod } n$  if it has the same remainder like  $a$  when divided by  $n$ . So,  $n$  divides  $(a-b)$ , and we write  $b \equiv a \text{ mod } n$ 
    - Examples:  $4 \equiv 11 \text{ mod } 7, \quad 25 \equiv 11 \text{ mod } 7, \quad 11 \equiv 25 \text{ mod } 7,$   
 $11 \equiv 4 \text{ mod } 7, \quad -10 \equiv 4 \text{ mod } 7$
  - As the remainder  $r$  of division by  $n$  is always smaller than  $n$ , we sometimes represent the set  $\{x \text{ MOD } n \mid x \in \mathbb{Z}\}$  by elements of the set  $\mathbb{Z}_n = \{0, 1, \dots, n - 1\}$

## Some Mathematical Background (2)

### Properties of Modular Arithmetic

Property	Expression
Commutative Laws	$(a + b) \text{ MOD } n = (b + a) \text{ MOD } n$ $(a \times b) \text{ MOD } n = (b \times a) \text{ MOD } n$
Associative Laws	$[(a + b) + c] \text{ MOD } n = [a + (b + c)] \text{ MOD } n$ $[(a \times b) \times c] \text{ MOD } n = [a \times (b \times c)] \text{ MOD } n$
Distributive Law	$[a \times (b + c)] \text{ MOD } n = [(a \times b) + (a \times c)] \text{ MOD } n$
Identities	$(0 + a) \text{ MOD } n = a \text{ MOD } n$ $(1 \times a) \text{ MOD } n = a \text{ MOD } n$
Inverses	$\forall a \in \mathbb{Z}_n: \exists (-a) \in \mathbb{Z}_n: a + (-a) \equiv 0 \text{ mod } n$ $p \text{ is prime} \Rightarrow \forall a \in \mathbb{Z}_p: \exists (a^{-1}) \in \mathbb{Z}_p: a \times (a^{-1}) \equiv 1 \text{ mod } p$

## Some Mathematical Background (3)

- Greatest common divisor:
  - $c = \text{gcd}(a, b) :\Leftrightarrow (c \mid a) \wedge (c \mid b) \wedge [\forall d: (d \mid a) \wedge (d \mid b) \Rightarrow (d \mid c)]$   
and  $\text{gcd}(a, 0) := |a|$
- The *gcd recursion theorem*:
  - $\forall a, b \in \mathbb{Z}^+: \text{gcd}(a, b) = \text{gcd}(b, a \text{ MOD } b)$
  - Proof:
    - As  $\text{gcd}(a, b)$  divides both  $a$  and  $b$  it also divides any linear combination of them, especially  $(a - \lfloor a/b \rfloor \times b) = a \text{ MOD } b$ ,  
so  $\text{gcd}(a, b) \mid \text{gcd}(b, a \text{ MOD } b)$
    - As  $\text{gcd}(b, a \text{ MOD } b)$  divides both  $b$  and  $a \text{ MOD } b$  it also divides any linear combination of them, especially  $\lfloor a/b \rfloor \times b + (a \text{ MOD } b) = a$ ,  
so  $\text{gcd}(b, a \text{ MOD } b) \mid \text{gcd}(a, b)$
- Euclidean Algorithm:
  - The algorithm *Euclid* given  $a, b$  computes  $\text{gcd}(a, b)$
  - *int Euclid(int a, b)*

```

{ if (b = 0) { return(a);}
  { return(Euclid(b, a MOD b);} }
                    
```

- Extended Euclidean Algorithm:
  - The algorithm *ExtendedEuclid* given  $a, b$  computes  $d, m, n$  such that:  
 $d = \text{gcd}(a, b) = m \times a + n \times b$
  - *struct*{int  $d, m, n$ } *ExtendedEuclid*(int  $a, b$ )  
 $\{ \text{int } d, d', m, m', n, n';$   
 $\text{if } (b = 0) \{ \text{return}(a, 1, 0); \}$   
 $(d', m', n') = \text{ExtendedEuclid}(b, a \text{ MOD } b);$   
 $(d, m, n) = (d', n', m' - \lfloor a / b \rfloor \times n');$   
 $\text{return}(d, m, n); \}$
  - Proof: (by induction)
    - Basic case  $(a, 0)$ :  $\text{gcd}(a, 0) = a = 1 \times a + 0 \times 0$
    - Induction from  $(b, a \text{ MOD } b)$  to  $(a, b)$ :
      - *ExtendedEuclid* computes  $d', m', n'$  correctly (induction hypothesis)
      - $d = d' = m' \times b + n' \times (a \text{ MOD } b) = m' \times b + n' \times (a - \lfloor a / b \rfloor \times b)$   
 $= n' \times a + (m' - \lfloor a / b \rfloor \times n') \times b$
  - The run time of *Euclid*( $a, b$ ) and *ExtendedEuclid*( $a, b$ ) is of  $O(\log b)$ 
    - Proof: see [Cor90a], section 33.2

- Summarizing the discussion of the Euclidean algorithms we have:

### Lemma 1:

Let  $a, b \in \mathbb{N}$  and  $d = \text{gcd}(a, b)$ . Then there exists  $m, n \in \mathbb{N}$  such that:  
 $d = m \times a + n \times b$

- We can use this lemma to prove the following:

### Theorem 1 (Euclid):

If a prime divides the product of two integers, then it divides at least one of the integers:  $p \mid (a \times b) \Rightarrow (p \mid a) \vee (p \mid b)$

- Proof: Let  $p \mid (a \times b)$

- If  $p \mid a$  then we are done.
- If not then  $\text{gcd}(p, a) = 1 \Rightarrow$   
 $\exists m, n \in \mathbb{N}: 1 = m \times p + n \times a$   
 $\Leftrightarrow b = m \times p \times b + n \times a \times b$

As  $p \mid (a \times b)$ ,  $p$  divides both summands of the equation and so it divides also the sum which is  $b$  ■

- A small, but nice excursion:
  - With the help of Theorem 1 the proof that  $\sqrt{2}$  is not a rational number can be given in a very elegant way:
 

Assume that  $\sqrt{2}$  can be expressed as a rational number  $m/n$  and that this fraction has been reduced such that  $\gcd(m, n) = 1$ :

$$\Rightarrow \sqrt{2} = \frac{m}{n} \Leftrightarrow 2 = \frac{m^2}{n^2} \Leftrightarrow 2n^2 = m^2$$

So, 2 divides  $m^2$ , and thus by Theorem 1 it also divides  $m$ , and so 4 divides  $m^2$ . But then 4 divides  $2n^2$  and, therefore, 2 divides also  $n^2$ .

Again by Theorem 1 this implies that 2 divides  $n$  and so 2 divides both  $m$  and  $n$ , which is a contradiction to the assumption that the fraction  $m/n$  is reduced.

■
  - And now to something more useful... – for cryptography :o)

### Theorem 2 (fundamental theorem of arithmetic):

Factorization into primes is unique up to order.

- Proof:
  - We will show that every integer with a non-unique factorization has a proper divisor with a non-unique factorization which leads to a clear contradiction when we finally have reduced to a prime number.
  - Let's assume that  $n$  is an integer with a non-unique factorization:

$$\begin{aligned} n &= p_1 \times p_2 \times \dots \times p_r \\ &= q_1 \times q_2 \times \dots \times q_s \end{aligned}$$

The primes are not necessarily distinct, but the second factorization is not simply a reordering of the first one.

As  $p_1$  divides  $n$  it also divides the product  $q_1 \times q_2 \times \dots \times q_s$ . By repeated application of Theorem 1 we show that there is at least one  $q_i$  which is divisible by  $p_1$ . If necessary reorder the  $q_i$ 's so that it is  $q_1$ . As both  $p_1$  and  $q_1$  are prime they have to be equal. So we can divide by  $p_1$  and we have that  $n/p_1$  has a non-unique factorization.

- We will use Theorem 2 to prove the following

### Corollary 1:

If  $\gcd(c, m) = 1$  and  $(a \times c) \equiv (b \times c) \pmod{m}$ , then  $a \equiv b \pmod{m}$

- Proof: As  $(a \times c) \equiv (b \times c) \pmod{m} \Rightarrow \exists n \in \mathbb{N}: (a \times c) - (b \times c) = n \times m$

$$\Leftrightarrow \underbrace{(a - b)}_{p_1 \times \dots \times p_i} \times \underbrace{c}_{q_1 \times \dots \times q_j} = \underbrace{n}_{r_1 \times \dots \times r_k} \times \underbrace{m}_{s_1 \times \dots \times s_l}$$

Please note that the p's, q's, r's and s's are prime and do not need to be distinct, but as  $\gcd(c, m) = 1$ , there are no indices  $g, h$  such that  $q_g = s_h$ .

So we can continuously divide the equation by all q's without ever "eliminating" one s and will finally end up with something like

$$\begin{aligned} \Leftrightarrow p_1 \times \dots \times p_i &= r_1 \times \dots \times r_o \times s_1 \times \dots \times s_l \\ &\quad \text{(note that there will be fewer r's)} \\ \Leftrightarrow (a - b) &= r_1 \times \dots \times r_o \times m \\ \Rightarrow a &\equiv b \pmod{m} \quad \blacksquare \end{aligned}$$

- Let  $\Phi(n)$  denote the number of positive integers less than  $n$  and relatively prime to  $n$ 
  - Examples:  $\Phi(4) = 2, \Phi(6) = 2, \Phi(7) = 6, \Phi(15) = 8$
  - If  $p$  is prime  $\Rightarrow \Phi(p) = p - 1$

### Theorem 3 (Euler):

Let  $n$  and  $b$  be positive and relatively prime integers, i.e.  $\gcd(n, b) = 1$   
 $\Rightarrow b^{\Phi(n)} \equiv 1 \pmod{n}$

Proof:

- Let  $t = \Phi(n)$  and  $a_1, \dots, a_t$  be the positive integers less than  $n$  which are relatively prime to  $n$ .  
 Define  $r_1, \dots, r_t$  to be the residues of  $b \times a_1 \pmod{n}, \dots, b \times a_t \pmod{n}$   
 that is to say:  $b \times a_i \equiv r_i \pmod{n}$ .

- Note that  $i \neq j \Rightarrow r_i \neq r_j$ .  
 If this would not hold, we would have  $b \times a_i \equiv b \times a_j \pmod{n}$   
 and as  $\gcd(b, n) = 1$ , Corollary 1 would imply  $a_i \equiv a_j \pmod{n}$  which can not be as  $a_i$  and  $a_j$  are by definition distinct integers between 0 and  $n$

Proof (continued):

- We also know that each  $r_i$  is relatively prime to  $n$  because any common divisor  $k$  of  $r_i$  and  $n$ , i.e.  $n = k \times m$  and  $r_i = p_i \times k$ , would also have to divide  $a_i$ ,
- as  $b \times a_i \equiv (p_i \times k) \pmod{(k \times m)} \Rightarrow \exists s \in \mathbb{N}: \quad (b \times a_i) - (p_i \times k) = s \times k \times m$   
 $\Leftrightarrow \quad (b \times a_i) = s \times k \times m + (p_i \times k)$

Because  $k$  divides each of the summands on the right-hand side and  $k$  does not divide  $b$  by assumption ( $n$  and  $b$  are relatively prime), it would also have to divide  $a_i$  which is supposed to be relatively prime to  $n$

- Thus  $r_1, \dots, r_t$  is a set of  $\Phi(n)$  distinct integers which are relatively prime to  $n$ . This means that they are exactly the same as  $a_1, \dots, a_t$ , except that they are in a different order. In particular, we know that  $r_1 \times \dots \times r_t = a_1 \times \dots \times a_t$
- We now use the congruence
 
$$r_1 \times \dots \times r_t \equiv b \times a_1 \times \dots \times b \times a_t \pmod{n}$$

$$\Leftrightarrow r_1 \times \dots \times r_t \equiv b^t \times a_1 \times \dots \times a_t \pmod{n}$$

$$\Leftrightarrow r_1 \times \dots \times r_t \equiv b^t \times r_1 \times \dots \times r_t \pmod{n}$$
- As all  $r_i$  are relatively prime to  $n$  we can use Corollary 1 and divide by their product giving:  $1 \equiv b^t \pmod{n} \Leftrightarrow 1 \equiv b^{\Phi(n)} \pmod{n}$  ■

### Theorem 4 (Chinese Remainder Theorem):

Let  $m_1, \dots, m_r$  be positive integers that are pairwise relatively prime, i.e.  $\forall i \neq j: \gcd(m_i, m_j) = 1$ . Let  $a_1, \dots, a_r$  be arbitrary integers.

Then there exists an integer  $a$  such that:

$$a \equiv a_1 \pmod{m_1}$$

$$a \equiv a_2 \pmod{m_2}$$

...

$$a \equiv a_r \pmod{m_r}$$

Furthermore,  $a$  is unique modulo  $M := m_1 \times \dots \times m_r$

Proof:

- For all  $i \in \{1, \dots, r\}$  we define  $M_i := (M / m_i)^{\Phi(m_i)}$
- As  $M_i$  is by definition relatively prime to  $m_i$  we can apply Theorem 3 and know that  $M_i \equiv 1 \pmod{m_i}$
- Since  $M_i$  is divisible by  $m_j$  for every  $j \neq i$ , we have  $\forall j \neq i: M_i \equiv 0 \pmod{m_j}$

Proof (continued):

- We can now construct the solution by defining:

$$a := a_1 \times M_1 + a_2 \times M_2 + \dots + a_r \times M_r$$

- The two arguments given above concerning the congruences of the  $M_i$  imply that  $a$  actually satisfies all of the congruences.
- To see that  $a$  is unique modulo  $M$ , let  $b$  be any other integer satisfying the  $r$  congruences. As  $a \equiv c \pmod n$  and  $b \equiv c \pmod n \Rightarrow a \equiv b \pmod n$  we have

$$\begin{aligned} & \forall i \in \{1, \dots, r\}: a \equiv b \pmod{m_i} \\ \Rightarrow & \forall i \in \{1, \dots, r\}: m_i \mid (a - b) \\ \Rightarrow & M \mid (a - b) \quad \text{as the } m_i \text{ are pairwise relatively prime} \\ \Leftrightarrow & a \equiv b \pmod M \end{aligned}$$

■

Lemma 2:

If  $\gcd(m, n) = 1$ , then  $\Phi(m \times n) = \Phi(m) \times \Phi(n)$

Proof:

- Let  $a$  be a positive integer less than and relatively prime to  $m \times n$ . In other words,  $a$  is one of the integers counted by  $\Phi(m \times n)$ .
- Consider the correspondence  $a \rightarrow (a \pmod m, a \pmod n)$

The integer  $a$  is relatively prime to  $m$  and relatively prime to  $n$  (if not it would divide  $m \times n$ ).

So,  $(a \pmod m)$  is relatively prime to  $m$  and  $(a \pmod n)$  is relatively prime to  $n$  as:  $a = \lfloor a / m \rfloor \times m + (a \pmod m)$ , so if there would be a common divisor of  $m$  and  $(a \pmod m)$ , this divisor would also divide  $a$ .

Thus every number  $a$  counted by  $\Phi(m \times n)$  corresponds to a pair of two integers  $(a \pmod m, a \pmod n)$ , the first one counted by  $\Phi(m)$  and the second one counted by  $\Phi(n)$ .

Proof (continued):

- Because of the second part of Theorem 4, the uniqueness of the solution  $a$  modulo  $(m \times n)$  to the simultaneous congruences:

$$a \equiv (a \text{ MOD } m) \text{ mod } m$$

$$a \equiv (a \text{ MOD } n) \text{ mod } n$$

we can deduce, that distinct integers counted by  $\Phi(m \times n)$  correspond to distinct pairs:

- Too see this, suppose that  $a \neq b$  counted by  $\Phi(m \times n)$  does correspond to the same pair  $(a \text{ MOD } m, a \text{ MOD } n)$ . This leads to a contradiction as  $b$  would also fulfill the congruences:

$$b \equiv (a \text{ MOD } m) \text{ mod } m$$

$$b \equiv (a \text{ MOD } n) \text{ mod } n$$

but the solution to these congruences is unique modulo  $(m \times n)$

Therefore,  $\Phi(m \times n)$  is at most the number of such pairs:

$$\Phi(m \times n) \leq \Phi(m) \times \Phi(n)$$

■

Proof (continued):

- Consider now a pair of integers  $(b, c)$ , one counted by  $\Phi(m)$  and the other one counted by  $\Phi(n)$ :

Using the first part of Theorem 4 we can construct a unique positive integer  $a$  less than and relatively prime to  $m \times n$ :

$$a \equiv b \text{ mod } m$$

$$a \equiv c \text{ mod } n$$

So, the number of such pairs is at most  $\Phi(m \times n)$ :

$$\Phi(m \times n) \geq \Phi(m) \times \Phi(n)$$

■

## The RSA Public Key Algorithm (1)

- The RSA algorithm was invented in 1977 by R. Rivest, A. Shamir and L. Adleman [RSA78] and is based on Theorem 3.
- Let  $p, q$  be distinct large primes and  $n = p \times q$ . Assume, we have also two integers  $e$  and  $d$  such that:
 
$$d \times e \equiv 1 \pmod{\Phi(n)}$$
- Let  $M$  be an integer that represents the message to be encrypted, with  $M$  positive, smaller than and relatively prime to  $n$ .
  - Example: Encode with <blank> = 99, A = 10, B = 11, ..., Z = 35  
So "HELLO" would be encoded as 1714212124.  
If necessary, break M into blocks of smaller messages: 17142 12124
- To encrypt, compute:  $E = M^e \pmod{n}$ 
  - This can be done efficiently using the *square-and-multiply algorithm*
- To decrypt, compute:  $M' = E^d \pmod{n}$ 
  - As  $d \times e \equiv 1 \pmod{\Phi(n)} \Rightarrow \exists k \in \mathbb{Z}: \begin{aligned} (d \times e) - 1 &= k \times \Phi(n) \\ \Leftrightarrow (d \times e) &= k \times \Phi(n) + 1 \end{aligned}$   
we have:  $M' \equiv E^d \equiv M^{(e \times d)} \equiv M^{(k \times \Phi(n) + 1)} \equiv 1^k \times M \equiv M \pmod{n}$

## The RSA Public Key Algorithm (2)

- As  $(d \times e) = (e \times d)$  the operation also works in the opposite direction, that means you can encrypt with  $d$  and decrypt with  $e$ 
  - This property allows to use the same keys  $d$  and  $e$  for:
    - Receiving messages that have been encrypted with one's public key
    - Sending messages that have been signed with one's private key
- To set up a key pair for RSA:
  - Randomly choose two primes  $p$  and  $q$  (of 100 to 200 digits each)
  - Compute  $n = p \times q$ ,  $\Phi(n) = (p - 1) \times (q - 1)$  (Lemma 2)
  - Randomly choose  $e$ , so that  $\gcd(e, \Phi(n)) = 1$
  - With the extended euclidean algorithm compute  $d$  and  $c$ , such that:  
 $e \times d + \Phi(n) \times c = 1$ , note that this implies, that  $e \times d \equiv 1 \pmod{\Phi(n)}$
  - The public key is the pair  $(e, n)$
  - The private key is the pair  $(d, n)$

## The RSA Public Key Algorithm (3)

- The security of the scheme lies in the difficulty of factoring  $n = p \times q$  as it is easy to compute  $\Phi(n)$  and then  $d$ , when  $p$  and  $q$  are known
- This class will not teach why it is difficult to factor large  $n$ 's, as this would require to dive deep into mathematics
  - If  $p$  and  $q$  fulfill certain properties, the best known algorithms are exponential in the number of digits of  $n$ 
    - Please be aware that if you choose  $p$  and  $q$  in an “unfortunate” way, there might be algorithms that can factor more efficiently and your RSA encryption is not at all secure:
      - Therefore,  $p$  and  $q$  should be about the same bitlength and sufficiently large
      - $(p - q)$  should not be too small
      - If you want to choose a small encryption exponent, e.g. 3, there might be additional constraints, e.g.  $\gcd(p - 1, 3) = 1$  and  $\gcd(q - 1, 3) = 1$
    - The security of RSA also depends on the primes generated being truly random (like every key creation method for any algorithm)
    - Moral: If you are to implement RSA by yourself, ask a mathematician or better a cryptographer to check your design

## Diffie-Hellman Key Exchange (1)

- The Diffie-Hellman key exchange was first published in the landmark paper [DH76], which also introduced the fundamental idea of asymmetric cryptography
- The DH exchange in its basic form enables two parties A and B to agree upon a *shared secret* using a public channel:
  - *Public channel* means, that a potential attacker E (E stands for eavesdropper) can read all messages exchanged between A and B
  - It is important, that A and B can be sure, that the attacker is not able to alter messages, as in this case he might launch a *man-in-the-middle attack*
  - The mathematical basis for the DH exchange is the problem of finding *discrete logarithms in finite fields*
  - The DH exchange is *not* an asymmetric encryption algorithm, but is nevertheless introduced here as it goes well with the mathematical flavor of this lecture... :o)

- Definition: *finite groups*
  - A group  $(S, \oplus)$  is a set  $S$  together with a binary operation  $\oplus$  for which the following properties hold:
    - *Closure*: For all  $a, b \in S$ , we have  $a \oplus b \in S$
    - *Identity*: There is an element  $e \in S$ , such that  $e \oplus a = a \oplus e = a$  for all  $a \in S$
    - *Associativity*: For all  $a, b, c \in S$ , we have  $(a \oplus b) \oplus c = a \oplus (b \oplus c)$
    - *Inverses*: For each  $a \in S$ , there exists a unique element  $b \in S$ , such that  $a \oplus b = b \oplus a = e$
  - If a group  $(S, \oplus)$  satisfies the commutative law  $\forall a, b \in S: a \oplus b = b \oplus a$  then it is called an *Abelian group*
  - If a group  $(S, \oplus)$  has only a finite set of elements, i.e.  $|S| < \infty$ , then it is called a *finite group*

- Examples:
  - $(\mathbb{Z}_n, +_n)$ 
    - with  $\mathbb{Z}_n := \{[0]_n, [1]_n, \dots, [n-1]_n\}$
    - where  $[a]_n := \{b \in \mathbb{Z} \mid b \equiv a \pmod{n}\}$  and
    - $+_n$  is defined such that  $[a]_n +_n [b]_n = [a + b]_n$

is a finite abelian group  
For the proof see the table showing the properties of modular arithmetic
  - $(\mathbb{Z}_n^*, \times_n)$ 
    - with  $\mathbb{Z}_n^* := \{[a]_n \in \mathbb{Z}_n \mid \gcd(a, n) = 1\}$ , and
    - $\times_n$  is defined such that  $[a]_n \times_n [b]_n = [a \times b]_n$

is a finite Abelian group. Please note that  $\mathbb{Z}_n^*$  just contains those elements of  $\mathbb{Z}_n$  that have a multiplicative inverse modulo  $n$   
For the proof see the properties of modular arithmetic

    - Example:  $\mathbb{Z}_{15}^* = \{[1]_{15}, [2]_{15}, [4]_{15}, [7]_{15}, [8]_{15}, [11]_{15}, [13]_{15}, [14]_{15}\}$ , as
 

$1 \times 1 \equiv 1 \pmod{15}$ ,	$2 \times 8 \equiv 1 \pmod{15}$ ,	$4 \times 4 \equiv 1 \pmod{15}$ ,
$7 \times 13 \equiv 1 \pmod{15}$ ,	$11 \times 11 \equiv 1 \pmod{15}$ ,	$14 \times 14 \equiv 1 \pmod{15}$

- If it is clear that we are talking about  $(\mathbb{Z}_n, +_n)$  or  $(\mathbb{Z}_n^*, \times_n)$  we often represent equivalence classes  $[a]_n$  by their representative elements  $a$  and denote  $+_n$  and  $\times_n$  by  $+$  and  $\times$ , respectively.
- Definition: *finite fields*
  - A *field*  $(S, \oplus, \otimes)$  is a set  $S$  together with two operations  $\oplus, \otimes$  such that
    - $(S, \oplus)$  and  $(S \setminus \{e_\oplus\}, \otimes)$  are commutative groups, i.e. only the identity element concerning the operation  $\oplus$  does not need to have an inverse regarding the operation  $\otimes$
    - For all  $a, b, c \in S$ , we have  $a \otimes (b \oplus c) = (a \otimes b) \oplus (a \otimes c)$
  - If  $|S| < \infty$  then  $(S, \oplus, \otimes)$  is called a *finite field*
- Example:
  - $(\mathbb{Z}_p, +_p, \times_p)$  is a finite field for each prime  $p$

- Definition: *primitive root, generator*
  - Let  $(S, \bullet)$  be a group,  $g \in S$  and  $g^a := g \bullet g \bullet \dots \bullet g$  ( $a$  times with  $a \in \mathbb{Z}^+$ )  
Then  $g$  is called a *primitive root* or *generator* of  $(S, \bullet)$   
 $:\Leftrightarrow \{g^a \mid 1 \leq a \leq |S|\} = S$
- Examples:
  - 1 is a primitive root of  $(\mathbb{Z}_n, +_n)$
  - 3 is a primitive root of  $(\mathbb{Z}_7^*, \times_7)$
- Not all groups do have primitive roots and those who have are called *cyclic groups*
- Theorem 5:  
 $(\mathbb{Z}_n^*, \times_n)$  does have a primitive root  $\Leftrightarrow n \in \{2, 4, p, 2 \times p^e\}$  where  $p$  is an odd prime and  $e \in \mathbb{Z}^+$ 
  - For the proof see [Niv80a]

□ Theorem 6:

If  $(S, \bullet)$  is a group and  $b \in S$  then  $(S', \bullet)$  with  $S' = \{b^a \mid a \in \mathbb{Z}^+\}$  is also a group.

- For the proof refer to [Cor90a] section 33.3
- As  $S' \subseteq S$ ,  $(S', \bullet)$  is called a *subgroup* of  $(S, \bullet)$
- If  $b$  is a primitive root of  $(S, \bullet)$  then  $S' = S$

□ Definition: order of a group and of an element

- Let  $(S, \bullet)$  be a group,  $e \in S$  its identity element and  $b \in S$  any element of  $S$ :
  - Then  $|S|$  is called the *order* of  $(S, \bullet)$
  - Let  $c \in \mathbb{Z}^+$  be the smallest element so that  $b^c = e$  (if such a  $c$  exists, if not set  $c = \infty$ ). Then  $c$  is called the *order* of  $b$ .

□ Theorem 7 (Lagrange):

If  $G$  is a finite group and  $H$  is a subgroup of  $G$ , then  $|H|$  divides  $|G|$ .  
Hence, if  $b \in G$  then the order of  $b$  divides  $|G|$ .

□ Theorem 8:

If  $G$  is a cyclic finite group of order  $n$  and  $d$  divides  $n$  then  $G$  has exactly  $\Phi(d)$  elements of order  $d$ . In particular,  $G$  has  $\Phi(n)$  elements of order  $n$ .

□ Theorems 5, 7, and 8 are the basis of the following algorithm that finds a cyclic group  $\mathbb{Z}_p^*$  and a primitive root  $g$  of it:

- Choose a large prime  $q$  such that  $p = 2q + 1$  is prime.
  - As  $p$  is prime, Theorem 5 states that  $\mathbb{Z}_p^*$  is cyclic.
  - The order of  $\mathbb{Z}_p^*$  is  $2 \times q$  and  $\Phi(2 \times q) = \Phi(2) \times \Phi(q) = q - 1$  as  $q$  is prime.
  - So, the odds of randomly choosing a primitive root are  $(q - 1) / 2q \approx 1 / 2$
  - In order to efficiently test, if a randomly chosen  $g$  is a primitive root, we just have to test if  $g^2 \equiv 1 \pmod{p}$  or  $g^q \equiv 1 \pmod{p}$ . If not, then its order has to be  $|\mathbb{Z}_p^*|$ , as Theorem 7 states that the order of  $g$  has to divide  $|\mathbb{Z}_p^*|$

- Definition: *discrete logarithm*
  - Let  $p$  be prime,  $g$  be a primitive root of  $(\mathbb{Z}_p^*, \times_p)$  and  $c$  be any element of  $\mathbb{Z}_p^*$ . Then there exists  $z$  such that:  $g^z \equiv c \pmod{p}$   
 $z$  is called the *discrete logarithm* of  $c$  modulo  $p$  to the base  $g$
  - Example 6 is the discrete logarithm of 1 modulo 7 to the base 3 as  
 $3^6 \equiv 1 \pmod{7}$
  - The calculation of the discrete logarithm  $z$  when given  $g$ ,  $c$ , and  $p$  is a computationally difficult problem and the asymptotical runtime of the best known algorithms for this problem is exponential in the bitlength of  $p$

- If Alice (A) and Bob (B) want to agree on a shared secret  $s$  and their only means of communication is a public channel, they can proceed as follows:
  - A chooses a prime  $p$ , a primitive root  $g$  of  $\mathbb{Z}_p^*$ , and a random number  $q$ :
    - A and B can agree upon the values  $p$  and  $g$  prior to any communication, or A can choose  $p$  and  $g$  and send them with his first message
    - A computes  $v = g^q \text{ MOD } p$  and sends to B:  $\{p, g, v\}$
  - B chooses a random number  $r$ :
    - B computes  $w = g^r \text{ MOD } p$  and sends to A:  $\{p, g, w\}$  (or just  $\{w\}$ )
  - Both sides compute the common secret:
    - A computes  $s = w^q \text{ MOD } p$
    - B computes  $s' = v^r \text{ MOD } p$
    - As  $g^{(q \times r)} \text{ MOD } p = g^{(r \times q)} \text{ MOD } p$  it holds:  $s = s'$
  - An attacker Eve who is listening to the public channel can only compute the secret  $s$ , if she is able to compute either  $q$  or  $r$  which are the discrete logarithms of  $v, w$  modulo  $p$  to the base  $g$

## Diffie-Hellman Key Exchange (3)

- If the attacker Eve is able to alter messages on the public channel, she can launch a *man-in-the-middle attack*:
  - Eve generates two random numbers  $q'$  and  $r'$ :
    - Eve computes  $v' = g^{q'} \text{ MOD } p$  and  $w' = g^{r'} \text{ MOD } p$
  - When A sends  $\{p, g, v\}$  she intercepts the message and sends to B:  $\{p, g, v'\}$
  - When B sends  $\{p, g, w\}$  she intercepts the message and sends to A:  $\{p, g, w'\}$
  - When the supposed “shared secret” is computed we get:
    - A computes  $s_1 = w'^q \text{ MOD } p = v'^r \text{ MOD } p$  the latter computed by E
    - B computes  $s_2 = v'^r \text{ MOD } p = w'^q \text{ MOD } p$  the latter computed by E
    - So, in fact A and E have agreed upon a shared secret  $s_1$  as well as E and B have agreed upon a shared secret  $s_2$
  - If the “shared secret” is now used by A and B to encrypt messages to be exchanged over the public channel, E can intercept all the messages and decrypt / re-encrypt them before forwarding them between A and B.

## Diffie-Hellman Key Exchange (4)

- Two countermeasures against the man-in-the-middle attack:
  - The shared secret is “*authenticated*” after it has been agreed upon
    - We will treat this in the section on key management
  - A and B use a so-called *interlock protocol* after agreeing on a shared secret:
    - For this they have to exchange messages that E has to relay before she can decrypt / re-encrypt them
    - The content of these messages has to be checkable by A and B
    - This forces E to invent messages and she can be detected
    - One technique to prevent E from decrypting the messages is to split them into two parts and to send the second part before the first one.
      - If the encryption algorithm used inhibits certain characteristics E can not encrypt the second part before she receives the first one.
      - As A will only send the first part after he received an answer (the second part of it) from B, E is forced to invent two messages, before she can get the first parts.
- Remark: In practice the number  $g$  does not necessarily need to be a primitive root of  $p$ , it is sufficient if it generates a large subgroup of  $\mathbb{Z}_p^*$

## The ElGamal Algorithm (1)

- ❑ The ElGamal algorithm can be used for both, encryption and digital signatures (see also [EIG85a] )
- ❑ Like the DH exchange it is based on the difficulty of computing discrete logarithms in finite fields
- ❑ In order to set up a key pair:
  - ❑ Choose a large prime  $p$ , a generator  $g$  of the multiplicative group  $\mathbb{Z}_p^*$  and a random number  $v$  such that  $1 \leq v \leq p - 2$ . Calculate:  $y = g^v \text{ mod } p$
  - ❑ The public key is  $(y, g, p)$
  - ❑ The private key is  $v$
- ❑ To sign a message  $m$ :
  - ❑ Choose a random number  $k$  such that  $k$  is relatively prime to  $p - 1$ .
  - ❑ Compute  $r = g^k \text{ mod } p$
  - ❑ With the Extended Euclidean Algorithm compute  $k^{-1}$ , the inverse of  $k \text{ mod } (p - 1)$
  - ❑ Compute  $s = k^{-1} \times (m - v \times r) \text{ mod } (p - 1)$
  - ❑ The signature over the message is  $(r, s)$

## The ElGamal Algorithm (2)

- ❑ To verify a signature  $(r, s)$  over a message  $m$ :
  - ❑ Confirm that  $y^r \times r^s \text{ MOD } p = g^m \text{ MOD } p$
  - ❑ Proof: We need the following
    - Lemma 3:  
Let  $p$  be prime and  $g$  be a generator of  $\mathbb{Z}_p^*$ .  
Then  $i \equiv j \text{ mod } (p - 1) \Rightarrow g^i \equiv g^j \text{ mod } p$   
Proof:  
–  $i \equiv j \text{ mod } (p - 1) \Rightarrow$  there exists  $k \in \mathbb{Z}^+$  such that  $(i - j) = (p - 1) \times k$   
– So,  $g^{(i-j)} = g^{(p-1) \times k} \equiv 1^k \equiv 1 \text{ mod } p$ , because of Theorem 3 (Euler)  
 $\Rightarrow g^i \equiv g^j \text{ mod } p$
  - So as
 

$s \equiv k^{-1} \times (m - v \times r)$	$\text{mod } (p - 1)$	
$\Leftrightarrow k \times s \equiv m - v \times r$	$\text{mod } (p - 1)$	
$\Leftrightarrow m \equiv v \times r + k \times s$	$\text{mod } (p - 1)$	
$\Rightarrow g^m \equiv g^{(v \times r + k \times s)}$	$\text{mod } p$	with Lemma 3
$\Leftrightarrow g^m \equiv g^{(v \times r)} \times g^{(k \times s)}$	$\text{mod } p$	
$\Leftrightarrow g^m \equiv y^r \times r^s$	$\text{mod } p$	

- Security of ElGamal signatures:
  - As the private key  $v$  is needed to be able to compute  $s$ , an attacker would have to compute the discrete logarithm of  $y$  modulo  $p$  to the basis  $g$  in order to forge signatures
  - It is crucial to the security, that a new random number  $k$  is chosen for every message, because an attacker can compute the secret  $v$  if he gets two messages together with their signatures based on the same  $k$  (see [Men97a], Note 11.66.ii)
  - In order to prevent an attacker to be able to create a message  $M$  with a matching signature, it is necessary not to sign directly the message  $M$  as explained before, but to sign a cryptographic hash value  $m = h(M)$  of it (these will be treated soon, see also [Men97a], Note 11.66.iii)

- To encrypt a message  $m$  using the public key  $(y, g, p)$ :
  - Choose a random  $k \in \mathbb{Z}^+$  with  $k < p - 1$
  - Compute  $r = g^k \text{ MOD } p$
  - Compute  $s = m \times y^k \text{ MOD } p$
  - The ciphertext is  $(r, s)$ , which is twice as long as  $m$
- To decrypt the message  $(r, s)$  using  $v$ :
  - Use the private key  $v$  to compute  $r^{(p-1-v)} \text{ MOD } p = r^{(-v)} \text{ MOD } p$
  - Recover  $m$  by computing  $m = r^{(-v)} \times s \text{ MOD } p$
  - Proof:
 
$$r^{(-v)} \times s \equiv r^{(-v)} \times m \times y^k \equiv g^{(-vk)} \times m \times y^k \equiv g^{(-v \times k)} \times m \times g^{(v \times k)} \equiv m \text{ mod } p$$
- Security:
  - The only known means for an attacker to recover  $m$  is to compute the discrete logarithm  $v$  of  $y$  modulo  $p$  to the basis  $g$
  - For every message a new random  $k$  is needed ([Men97a], Note 8.23.ii)

## Elliptic Curve Cryptography (1)

- The algorithms presented so far have been invented for the multiplicative group  $(\mathbb{Z}_p^*, \times_p)$  and the field  $(\mathbb{Z}_p, +_p, \times_p)$ , respectively
- It has been found during the 1980's that they can be generalized and be used with other groups and fields as well
- The main motivation for this generalization is:
  - A lot of mathematical research in the area of primality testing, factorization and computation of discrete logarithms has led to techniques that allow to solve these problems in a more efficient way, if certain properties are met:
    - When the RSA-129 challenge was given in 1977 it was expected that it will take some 40 quadrillion years to factor the 129-digit number ( $\approx 428$  bit)
    - In 1994 it took 8 months to factor it by a group of computers networked over the Internet, calculating for about 5000 MIPS-years
    - Advances in factoring algorithms allowed 2009 to factor a 232-digit number (768 bit) in about 1500 AMD64-years [KAFL10]
  - ⇒ the key length has to be increased (currently about 2048 bit)

## Elliptic Curve Cryptography (2)

- Motivation (continued):
  - Some of the more efficient techniques do rely on specific properties of the algebraic structures  $(\mathbb{Z}_p^*, \times_p)$  and  $(\mathbb{Z}_p, +_p, \times_p)$
  - Different algebraic structures may therefore provide the same security with shorter key lengths
- A very promising structure for cryptography can be obtained from the *group of points on an elliptic curve over a finite field*
  - The mathematical operations in these groups can be efficiently implemented both in hardware and software
  - The discrete logarithm problem is believed to be hard in the general class obtained from the group of points on an elliptic curve over a finite field

- Algebraic group consisting of
  - Points on Weierstrass' Equation:  $y^2 = x^3 + ax + b$
  - Additional point O in "infinity"
- May be calculated over  $\mathbb{R}$ , but in cryptography  $\mathbb{Z}_p$  and  $GF(2^n)$  are used
- Already in  $\mathbb{R}$  arguments influence form significantly:
  - $y^2 = x^3 - 3x + 5$
  - $y^2 = x^3 - 40x + 5$

- Addition of elements = Addition of points on the curve
- Geometric interpretation:
  - Each point P: (x,y) has an inverse -P: (x,-y)
  - A line through two points P and Q usually intersects with a third point R
  - Generally, sum of two points P and Q equals -R

- The additional point O is the neutral element, i.e.,  $P + O = P$
- $P + (-P)$ :
  - If the inverse point is added to P, the line and curve intersect in “infinity”
  - By definition:  $P + (-P) = O$
- $P + P$ : The sum of two identical points P is the inverse of the intersecting point with the tangent through P:

- If one of the summands is O, the sum is the other summand
- If the summands are inverse to each other the sum is O
- For the more general cases the slope of the line is:

$$\alpha = \begin{cases} \frac{y_Q - y_P}{x_Q - x_P} & \text{for } P \neq -Q \wedge P \neq Q \\ \frac{3x_P^2 + a}{2y_P} & \text{for } P = Q \end{cases}$$

- Result of point addition, where  $(x_r, y_r)$  is already the reflected point (-R)

$$x_r = \alpha^2 - x_p - x_q$$

$$y_r = \alpha(x_p - x_r) - y_p$$

- ❑ Multiplication of natural number  $n$  and point  $P$  performed by multiple repeated additions
- ❑ Numbers are grouped into powers of 2 to achieve logarithmic runtime, e.g.  $25P = P + 8P + 16P$
- ❑ This is possible if and only if the  $n$  is known!
- ❑ If  $n$  is unknown for  $nP = Q$ , a logarithm has to be solved, which is possible if the coordinate values are chosen from  $\mathbb{R}$
  
- ❑ For  $\mathbb{Z}_p$  and  $GF(2^n)$  the discrete logarithm problem for elliptic curves has to be solved, which cannot be done efficiently!
  
- ❑ *Note:* it is not defined how two points are multiplied, but only a natural number  $n$  and point  $P$

- ❑ Over  $\mathbb{Z}_p$  the curve degrades to a set of points
- ❑ For  $y^2 \equiv x^3 - 3x + 5 \pmod{19}$  :

- ❑ *Note:* For some  $x$  values, there is no  $y$  value!

- In general a little bit more problematic: determine the y-values for a given x (as its square value is calculated) by  $y^2 \equiv f(x) \pmod{p}$
- Hence p is often chosen s.t.  $p \equiv 3 \pmod{4}$
- Then y is calculated by  $y_1 \equiv f(x)^{\frac{p+1}{4}} \pmod{p}$  and  $y_2 \equiv -f(x)^{\frac{p+1}{4}} \pmod{p}$  if and only if a solution exists at all
- Short proof:
  - From the Euler Theorem 3 we know that  $f(x)^{p-1} \equiv 1 \pmod{p}$
  - Thus the square root must be 1 or -1  $f(x)^{\frac{p-1}{2}} \equiv \pm 1 \pmod{p}$
  - Case 1:  $f(x)^{\frac{p-1}{2}} \equiv 1 \pmod{p}$ 
    - Multiply both sides by f(x):  $f(x)^{\frac{p+1}{2}} \equiv f(x) \equiv y^2 \pmod{p}$
    - As p + 1 is divisible by 4 we can take the square root so that  $f(x)^{\frac{p+1}{4}} \equiv y \pmod{p}$  ■
  - Case 2: In this case no solution exists for the given x value (as shown by Euler)

- Due to the discrete structure point mathematical operations do not have a geometric interpretation any more, but
- Algebraic addition similar to addition over  $\mathbb{R}$
- If the inverse point is added to P, the line and “curve” still intersect in “infinity”
- All x- and y-values are calculated mod p
- Division is replaced by multiplication with the inverse element of the denominator
  - Use the Extended Euclidean Algorithm with w and p to derive the inverse -w
- Algebraic multiplication of a natural number n and a point P is also performed by repeated addition of summands of the power of 2
- The discrete logarithm problem is to determine a natural number n in  $nP = Q$  for two known points P and Q

- ❑ Please note that the order of a group generated by a point on a curve over  $\mathbb{Z}_p$  is not  $p-1$ !
- ❑ Determining the exact order is not easy, but can be done in logarithmic time by Schoofs algorithm [Sch85] (requires much more mathematical background than desired here)
- ❑ But Hasse's theorem on elliptic curves states that the group size  $n$  must lay between:
  - ❑  $p + 1 - 2\sqrt{p} \leq n \leq p + 1 + 2\sqrt{p}$
- ❑ As mentioned before: Generating rather large groups is sufficient

- ❑ The Diffie-Hellman-Algorithm can easily be adapted to elliptic curves
- ❑ If Alice (A) and Bob (B) want to agree on a shared secret  $s$ :
  - ❑ A and B agree on a cryptographically secure elliptic curve and a point  $P$  on that curve
  - ❑ A chooses a random number  $q$ :
    - A computes  $Q = q P$  and transmits  $Q$  to Bob
  - ❑ B chooses a random number  $r$ :
    - B computes  $R = r P$  and transmits  $R$  to Alice
  - ❑ Both sides compute the common secret:
    - A computes  $S = q R$
    - B computes  $S' = r Q$
    - As  $q r P = r q P$  the secret point  $S = S'$
- ❑ Attackers listening to the public channel can only compute  $S$ , if able to compute either  $q$  or  $r$  which are the discrete logarithms of  $Q$  and  $R$  for the point  $P$

- ❑ Adapting ElGamal for elliptic curves is rather straight forward for the encryption routine
- ❑ To set up a key pair:
  - ❑ Choose an elliptic curve over a finite field, a point  $G$  that generates a large group, and a random number  $v$  such that  $1 < v < n$ , where  $n$  denotes to the size of the induced group, Calculate:  $Y = vG$
  - ❑ The public key is  $(Y, G, \text{curve})$
  - ❑ The private key is  $v$

- ❑ To encrypt a message:
  - ❑ Choose a random  $k \in \mathbb{Z}^+$  with  $k < n - 1$ , compute  $R = kG$
  - ❑ Compute  $S = M + kY$ , where  $M$  is a point derived by the message
    - Problem: Interpreting the message  $m$  as a  $x$  coordinate of  $M$  is not sufficient, as the  $y$  value does not have to exist
    - Solution from [Ko87]: Choose a constant  $c$  (e.g. 100) check if  $cm$  is the  $x$  coordinate of a valid point, if not try  $cm+1$ , then  $cm+2$  and so on
    - To decode  $m$ : take the  $x$  value of  $M$  and do an integer division by  $c$  (receiver has to know  $c$  too)
  - ❑ The ciphertext are the points  $(R, S)$
  - ❑ Twice as long as  $m$ , if stored in so-called *compressed form*, i.e. only  $x$  coordinates are stored and a single bit, indicating whether the larger or smaller corresponding  $y$ -coordinate shall be used
- ❑ To decrypt a message:
  - ❑ Derive  $M$  by calculating  $S - vR$
  - ❑ Proof:  $S - vR = M + kY - vR = M + kvG - vkG = M + O = M$

- ❑ To sign a message:
  - ❑ Choose a random  $k \in \mathbb{Z}^+$  with  $k < n - 1$ , compute  $R = kG$
  - ❑ Compute  $s = k^{-1}(m + rv) \bmod n$ , where  $r$  is the x-value of  $R$
  - ❑ The signature are  $(r, s)$ , again about as twice as long as  $n$
- ❑ To verify a signed message:
  - ❑ Check if the *point*  $P = ms^{-1}G + rs^{-1}Y$  has the x-coordinate  $r$
  - ❑ *Note*:  $s^{-1}$  is calculated by the Extended Euclidian Algorithm with the input  $s$  and  $n$  (the order of the group)
  - ❑ Proof:  $ms^{-1}G + rs^{-1}Y = ms^{-1}G + rs^{-1}vG = (m + rv)(s^{-1})G = (ks)(s^{-1})G = kG = R$
- ❑ Security discussion:
  - ❑ As in the original version of ElGamal it is crucial to not use  $k$  twice
  - ❑ Messages should not be signed directly
  - ❑ Further checks may be required, i.e.,  $G$  must not be  $O$ , a valid point on the curve etc. (see [NIST09] for further details)

- ❑ The security heavily depends on the chosen curve and point:
  - ❑ The discriminant of the curve must not be zero, i.e.,  $4a^3 + 27b^2 \not\equiv 0 \pmod{p}$  otherwise the curve is degraded (a so called *singular curve*)
  - ❑ Menezes et. al. have found a sub-exponential algorithm for so-called *supersingular elliptic curves* but this does not work in the general case [Men93a]
- ❑ The constructed algebraic groups should have as many elements a possible
- ❑ This class will not go into more details of elliptic curve cryptography as this requires way more mathematics than desired for this course... :o)
- ❑ For non-cryptographers it is best to depend on predefined curves, e.g., [LM10] or [NIST99] and standards such as ECDSA
- ❑ Many publications choose parameters  $a$  and  $b$  such that they are provably chosen by a random process (e.g. publish  $x$  for  $h(x) = a$  and  $y$  for  $h(y) = b$ ); Shall ensure that the curves do not contain a cryptographic weakness that only the authors knows about

- ❑ The security depends on the length of  $p$ 
  - ❑ Key lengths with comparable strengths according to [NIST12]:

Symmetric Algorithms	RSA	ECC
112	2048	224-255
128	3072	256-383
192	7680	384-511
256	15360	> 512

- ❑ The security also heavily depends on the implementation!
  - ❑ The different cases (e.g. with 0) in ECC calculation may be observable, i.e., power consumption and timing differences
  - ❑ Attackers might deduct side-channel attacks, as in OpenSSL 0.9.8o [BT11]
    - Attacker may deduce the bit length of a value  $k$  in  $kP$  by measuring the time required for the square and multiply algorithm
    - Algorithm was aborted early in OpenSSL when no further bits were set to “1”
  - ❑ Attackers might try to generate invalid points to derive facts about the used key as in OpenSSL 0.9.8g, leading to a recovery of a full 256-bit ECC key after only 633 queries [BBP12]
- ❑ *Lesson learned:* Do not do it on your own, unless you have to and know what you are doing!

- ❑ As mentioned earlier it is possible to construct cryptographic elliptic curves over  $G(2^n)$ , which may be faster in hardware implementations
  - ❑ We refrained from details as this would not have brought many different insights!
- ❑ Elliptic curves and similar algebraic groups are an active field of research and allow other advanced applications e.g.:
  - ❑ So-called Edwards Curves are currently discussed, as they seem more robust against side-channel attacks (e.g. [BLR08])
  - ❑ Bilinear pairings allow
    - Programs to verify that they belong to the same group, without revealing their identity (Secret handshakes, e.g. [SM09])
    - Public keys to be structured, e.g. use “Alice” as public key for Alice (Identity based encryption, foundations in [BF03])
- ❑ Before deploying elliptic curve cryptography in a product, make sure to not violate patents, as there are still many valid ones in this field!

- ❑ Asymmetric cryptography allows to use two different keys for:
  - ❑ Encryption / Decryption
  - ❑ Signing / Verifying
- ❑ The most practical algorithms that are still considered to be secure are:
  - ❑ RSA, based on the difficulty of factoring and solving discrete logarithms
  - ❑ Diffie-Hellman (not an asymmetric algorithm, but a key agreement protocol)
  - ❑ ElGamal, like DH based on the difficulty of computing discrete logarithms
- ❑ As their security is entirely based on the difficulty of certain mathematical problems, algorithmic advances constitute their biggest threat
- ❑ Practical considerations:
  - ❑ Asymmetric cryptographic operations are about magnitudes slower than symmetric ones
  - ❑ Therefore, they are often not used for encrypting / signing bulk data
  - ❑ Symmetric techniques are used to encrypt / compute a cryptographic hash value and asymmetric cryptography is just used to encrypt a key / hash value
