

Protection of Communication Infrastructures Chapter 5 Secure Name Resolution

- DNS Security Issues
- DNSSEC
- Alternative Approaches

Protection (SS 2023): 05 - Secure Name Resolution

Security of the Domain Name System

- Vital service for the Internet
 - "Do you know the IP-Address of your mail server?"
 - "You know you should not follow the link

http://very.malicio.us

but what about

http://www.yourbank.de ??"

- But: DNS does not support
 - Data integrity
 - Data origin authentication
 - □ (Confidentiality)
- Threats:
 - Data Authenticity/Integrity
 - Denial of Service

[Acknowledgement: Thanks to Thorsten Strufe for help in preparing this material.]

DNS – The Domain Name System

□ Naming service for (almost all) Internet traffic

http://v

Postbank

Homepage Konten • Karter

Versichern Vorsorgen

Online Services Mobile Services

Vermögensberatun Altersvorsorge

Kredite Anlegen • Sparen Fonds • Börse Bausparen • Baufinanzierung

- □ Lookup of (resolve)
 - IP addresses
 - Mail servers
 - Alias names
 - Alternative name servers
 - ...
- Decentralized database consisting of multitude of servers

Protection (SS 2023): 05 - Secure Name Resolution

TELEMATIK DNS – Data Organization: Domains / Zones Rechnernetze Root Domain Server **DENIC** Server Internic org com de Server google apple zeit bund Bundesbmbf bsi WWW maps verwaltungsamt Google Server WWW Structured Namespace Hierarchical organization in sub domains/zones □ Sourced at "root zone" (". ") □ Parent zones maintain pointers to child zones ("zone cuts") Zone data is stored as "Resource Records" (RR)

Be

DNS – Components

Authoritative Server

TELEMATIK

hnernetze

- Server maintaining authoritative content of a complete DNS zone
- Top-Level-Domain (TLD) servers & auth servers of organization's domains
- Pointed to in parent zone as authoritative
- Possible load balancing: master/slaves
- □ Recursive (Caching) Server
 - □ Local proxy for DNS requests
 - Caches content for specified period of time (soft-state with TTL)
 - If data not available in the cache, request is processed recursively
- □ Resolver
 - □ Software on client's machines (part of the OS)
 - □ Windows, MacOS, and *nix: Stub resolvers
 - Delegate request to local server
 - Recursive requests only, usually no iterative requests

Protection (SS 2023): 05 - Secure Name Resolution

DNS – Resource Records

- □ Atomic entries in DNS are called "Resource Records" (RR)
- □ Format:

<name> [<ttl>] [<class>] <type> <rdata>

- name (domain name of resource)
- □ ttl (Time-to-live)
- □ class (used protocol): IN (Internet), CH (Chaosnet)...
- type (record type): A (Host-Address), NS (Name Server), MX (Mail Exchange), CNAME (Canonical Name), AAAA (IPv6-Host-Address), DNAME (CNAME, IPv6)
- □ rdata (resource data): Content! (What did we want to look up?)

6

DNS – Header Fields

- Identifier: a 16-bit identification field generated by the device that creates the DNS query. It is copied by the server into the response, so it can be used by that device to match that query to the corresponding reply
- Query/Response Flag: differentiates between queries and responses (0 ~ Query, 1 ~ Response)
- Operation Code: specifies the type of message (Query, Status, Notify, Update)
- □ Authoritative Answer Flag (AA): set to1 if the answer is authoritative
- Truncation Flag: When set to 1, indicates that the message was truncated due to its length (might happen with UDP, requestor can then decide to ask again with TCP as transport service)
- □ *Recursion Desired:* set to 1 if requester desired recursive processing
- □ *Recursion Available:* set to 1 if server supports recursive queries

Protection (SS 2023): 05 - Secure Name Resolution

- □ Authentication and integrity of name mappings
 - Most prominent thread: Cache Poisoning
 - □ Simple Countermeasures:
 - Random Port Numbers, Split-Horizon DNS, no PMTUD...
 - Cryptographic countermeasures
 - Data Integrity with TSIG records
 - DNSSEC
- Availability
 - DNS being a target of DoS attacks
 - DNS being a mean of amplification attacks

□ (Confidentiality & Access Control)

Protection (SS 2023): 05 - Secure Name Resolution

11

Threats to DNS: Denial of Service

- DNS itself as vital service a "worthy" target
 - Without DNS most Internet services will not work (usage of names rather than IP-Addresses for numerous reasons!)
 - DDoS Attacks on root servers: via notorious "typos" in TLDs
 - Extremely difficult to trace back!
- DNS Amplification Attacks
 - Spoofed queries (60 Bytes) may generate potentially large responses (4KBytes)
 - Exploit open recursive servers to generate load on other DNS servers
 - Exploit open servers as reflectors when flooding a victim with traffic (via source IP Address spoofing in request)

Robustness towards DDoS

- General issues
 - Secure DNS server
 - OS selection and updates
 - Firewalls
 - Server software selection and updates
 - Redundancy and over provisioning
 - Root ".": 13 name server "names"
 ({a..m}.root-servers.net)
 - "com", "net" 13 name servers each, "de" 16 name servers
 - Anycast
 - Announcement of an IP prefix from multiple locations
 - Requests from different parts of the internet are routed to different machines with the same IP address
 - Done by 11 of the 13 root-servers

Protection (SS 2023): 05 - Secure Name Resolution

Protection (SS 2023): 05 - Secure Name Resolution

Threats to DNS: Data Corruption / Cache Poisoning

□ All resolved RRs are cached at local DNS servers

TELEMATIK

Rechnernetze

DNS slave servers replicate zone data from master

DNS Threats – Cache Poisoning: Simple Poisoning (1)

- Attack: put fake data in slaves / caching servers (and nobody will realize the redirection from www.yourbank.de to very.malicio.us ...)
- DNS via UDP, no handshakes for connection establishment
- Transactions in DNS only through tuple of

<auth server(ip address), auth server(port), transaction id>

- With knowledge about transactions distribute malicious data
- □ **IP Address** of authoritative name servers are well known
- □ In many implementations same **port** for all transactions
- □ **Q-ID** unknown, *but*: servers used to choose them sequentially...

DNS Threats – Cache Poisoning: Simple Poisoning (2)

Mitigation of Cache Poisoning

- □ Random ports for each transaction (BIND8)
 - □ Since Version 8 BIND uses PRNG for port number and query id selection
 - However PRNG == Pseudo Random Number Generator, with knowledge about previous port numbers future port numbers can be guessed if PRNG not cryptographically secure (see network security course chapter 6)
- □ More random ports for each transaction (BIND9)
 - □ New and better PRNG since BIND9, random numbers are harder to guess
- □ Cache Poisoning usually only after aging of entry in local DNS server
 - □ Only if attacker attacks at the right moment, he can poison the cache
 - Typical TTL:
 - 172800 (2d) for most name servers
 - Seconds to hours for A-Entries of organizations (tu-ilmenau.de 4h, deutschebank.de 30min, commerzbank.de 60mins, postbank.de 60s)
- □ Nevertheless: cache poisoning is still not solved completely!

Cache Poisoning with "Brute Force"

TELEMATIK

hnernetze

- 1. Attacker sends multitude of requests for targeted domain to local DNS server of victim and
- 2. Attacker sends multitude of fake replies with IP and port from auth server of targeted domain, guessing transaction id for one of the recursive requests from local caching server to auth server $(2^{16} \times 2^{16} = 2^{32} \approx 4 \text{ billion possible combinations in theory})$
- 3. Victim requests data about targeted domain
- 4. Local caching server responds with fake data

More Sophisticated Cache Poisoning

- □ Usually not a high number of chances when TTL high, e.g., 1 day
- □ But there is a trick [Kam08]
- □ Imagine an attacker M:
 - □ M → Cache: Give me kslkskdf.bank.com (kslkskdf being a random value)
 - □ The Cache Server must now ask the Authoritative Server at bank.com
 - □ M → Cache: Not responsible for kslkskdf.bank.com, but www.bank.com is. You may reach www.bank.com at 141.24.212.114 (with 141.24.212.114 being the address of the attacker)
 - The cache will now ask 141.24.212.114 for kslkskdf.bank.com and will also remember the "name server" www.bank.com
- □ Even the ideal entropy of 2³² is insufficient!

More Sophisticated Cache Poisoning - Defense

- □ How can we increase the entropy of DNS queries?
- Idea: DNS does not distinguish between upper and lower case, encode more bits in the name [DAV+08]
- Now the same attack:
 - □ M → Cache: Give me kslkskdf.bank.com
 - □ The Cache Server must now ask the Authoritative Server at bank.com Cache → Auth Server: Give me kSLkSkdF.bAnK.COM
 - □ M → Cache: Not responsible for kslkskdf.bank.com, but www.bank.com is. You may reach www.bank.com at 141.24.212.114. (Ignored as kslkskdf.bank.com does not match the case of the query)
 - □ Auth Server → Cache: kSLkSkdF.bAnK.COM is unknown
- □ Entropy is increased to 2³²⁺ⁿ for n being the letters in a domain name
- □ Helps for www.deutsche-bank.de but not much for db.com

Protection (SS 2023): 05 - Secure Name Resolution

Most Sophisticated Cache Poisoning

- DNS is usually transported over UDP, which may fragment
- □ What happens when a DNS reply gets fragmented?
 - Random port numbers, Query ID and perhaps the original question (e.g. kSLkSkdF.bAnK.COM) are in the first fragment
 - Depending on the query and the MTU the actual answer may be in the second fragment
 - □ Fragments are matched by a 16 bit identification field...
- □ Attackers thus can try to [HS13b]
 - □ Find queries leading to large answers
 - Spoof PTMU related ICMP messages to set the fragmentation boundary
 - □ Send a "second" fragment with different identifications to the cache
 - Send the query to the cache
 - Wait for the cache to reassemble the reply and the crafted second fragment...
- DNS server should avoid large answers and PMTU discovery...

Robustness towards Data Corruption: Split-Horizon DNS (1)

- Goal: Avoid cache poisoning from external machines
- □ Idea: Split the name service functions
 - Name resolution (look up of DNS info)
 - Domain information (Auth service of local DNS info)
- Internal server
 - Implements name resolution
 - Performs recursive look-ups at remote DNS servers
 - Located behind firewall and only accepts requests from local LAN
- External server
 - Authoritative server of domain
 - Accepts remote requests but *never accepts* remote updates
- Zone transfer from external to internal server allowed

Protection (SS 2023): 05 - Secure Name Resolution

Robustness towards Data Corruption: Data Integrity

- Secret Key Transaction Authentication for DNS (TSIG) [VGE00]
- $\hfill\square$ Usage of signatures to secure data at zone transfer master \rightarrow slave
- Symmetric keys between entities
 - MD5 Hash used as signature or
 - □ HMAC with SHA-1 and SHA-2 [Eas06]
- TSIG Resource Record: (Name, Type ("TSIG"), Class ("ANY"), TTL("0"), Length, Data(<signature>))
- Possibility to authenticate, but very complex to administrate in large domains (manual pre-sharing of keys) amount of keys required: n x (n-1) / 2
- □ Kerberos may help [Eas00], but not on global scope...
- Main application area: Secure communication between authoritative and backup servers

Protection (SS 2023): 05 - Secure Name Resolution

- DNSSEC aims at:
 - □ End-to-end zone data origin authentication and integrity
 - in a global scope
 - without breaking the established DNS mechanisms
- DNSSEC does not provide:
 - □ Availability (in fact, it facilitates DoS Attacks on DNS servers)
 - □ Confidentiality
 - Controlled Access (makes it even worse)
 - Guarantee for correctness of data (only that it has been signed by some authoritative entity)

Rechnerpetze DNSSEC – Overview

- Usage of public key cryptography for data origin authentication on a world wide scale
- □ Use of DNS itself to distribute signatures and keys!
- RRSets (groups of RRs) are signed with the private key of authoritative entities
- Public keys (DNSKEYs) published using DNS
- Child zone keys are authenticated by parents (according to the zone hierarchy) and hence anchored *trust chains* established
- Only root zone key signing key (KSK) needed (manual distribution) to create complete trust hierarchy (for supported zones)
- □ No key revocation → DNSSEC keys should have short expiration date (quick rollover)

Protection (SS 2023): 05 - Secure Name Resolution

TELEMATIK **DNSSEC – Means of Securing RRSets** chnernetze

- Goal: authenticity and integrity of Resource Record Sets
- Means:
 - Public Key Cryptography (with Trust Chains)
 - Security integrated in DNS (new RRs)
- New Resource Record Types:
 - □ RRSiq: RR for signatures to transmitted RRs
 - DNSKEY: RR for transmission of public keys
 - DS: RR for trust chaining (Trust Anchor signs Key of Child Zone)
 - □ NSEC: RR for next secure zone in canonical order (authenticated denial for requested zone; introduces new confidentiality/privacy problems)
 - □ NSEC3: RR for next secure zone in canonical order (hashed)

Protection (SS 2023): 05 – Secure Name Resolution

TELEMATIK DNS – Authority Delegation and Trust Chaining nnernetze

DNS – Authority Delegation and Trust Chaining (Example)

31

Protection (SS 2023): 05 – Secure Name Resolution

DNSSEC Deployment

- KSK for Root Zone
 - □ Stored in two redundant Hardware Security Modules (HSM)
 - □ Each activated by 3 out 7 international experts (Crypto Officers)
 - Recovery by 5 out of 7 different international experts (*Recovery Key Share Holder*)
 - □ Sign ZSK for root zone (under control of Verisign, a US company...)
- In Subzones: Splitting KSK and ZSK allows for different security levels
 - □ KSK generates long-living signatures (stored offline)
 - ZSK generates short-living signatures ("accessible" system)
 - But what if ZSK becomes compromised?
 - Cannot change ZSK quickly (as KSK signatures are long living)
 - Asking provider to change KSK is quicker...
 - Sense of splitting?!

DNSSEC – New Resource Records: RRSIG

□ Resource Record for transmission of signatures

□ RRSIG:

- □ Name name of the signed RR
- □ _{Type} RRSIG (46)
- Algorithm DSA (3), RSASHA1 (5), RSASHA1-NSEC3-SHA1(7) RSASHA256 (8), ECDSAP256SHA256 (13)...
- Labels number of labels in original RR (to differentiate wildcards)
- □ TTL TTL at time of signature (for later reconstruction)
- □ Signature Expiration End of validity period of signature
- □ Signature Inception Beginning of validity period of signature
- □ Key Tag ID of used key if signer owns multiple keys
- □ Signer's Name DNS Name of the signer
- □ Signature Actual Signature

Protection (SS 2023): 05 – Secure Name Resolution

Resource Record containing public keys for distribution

DNSKEY:

- □ Label Name of key owner
- □ Class Always IN (3)
- □ _{Type} DNSKEY (48)
- □ Flags key types: KSK (257) or ZSK (256)
- □ Protocol Always DNSSEC (3)
- Algorithm DSA (3), RSASHA1 (5), RSASHA1-NSEC3-SHA1(7), RSASHA256 (8), ECDSAP256SHA256 (13)...
- □ Key Actual key

DNSSEC – New Resource Records: DS

- DS contains hash-value of DNSKEY of the name server of a sub zone
- □ Together with NS Resource Record, DS is used for trust chaining

DS (Delegation Signer)		
Name	 Name of the chained sub zone 	
🛛 Туре	– DS (43)	
🛛 Key Tag	 Identification of the hashed key 	
Algorithm	 – DSA (3), RSASHA1 (5), RSASHA1-NSEC3- SHA1(7), RSASHA256 (8), ECDSAP256SHA256 (13) 	
<pre>Digest Type Digest</pre>	 SHA-1(1), SHA-256(2) Actual value of hashed DNSKEY 	

DNSSEC – New Resource Records: NSEC

- Next Secure (NSEC) gives information about the next zone / sub domain in canonical order (last entry points to first entry for the construction of a closed ring)
- Gives the ability to prove the non-existence of a DNS entry: *Authenticated Denial*
- □ NSEC
 - □ Name Name of the signed RR
 - □ _{Type} NSEC (47)
 - Dext Domain Name of the next domain in alphabetical order
- Authenticated denial with NSEC gives the possibility to "walk" the chain of NSEC and to gain knowledge on the full zone content (all zones/ sub domains) in O(N)
 - This may be a privacy violation

DNSSEC – New Resource Records: NSEC3 (1)

- Successor to NSEC: NSEC3 and NSEC3PARAM [LSA08]
- Uses hashed domain names to make zone walking more difficult
- Hashing based on salt and multiple iterations to make dictionary attacks more difficult

□ NSEC3

Name	 Name of the signed RR
Туре	– NSEC3 (50)
Hash Algorith	m – SHA-1 (1)
Flags	 To Opt-Out unsigned names
Iterations	 Number of iterations of Hash Algorithm
Salt Length	 Length of the salt value
Salt	 Actual salt value
Hash Length	 Output length of hash function
Next Hashed O	wner Name - Next Hash of domain name in
	alphabetical order

Protection (SS 2023): 05 - Secure Name Resolution

DNSSEC – New Resource Records: NSEC3 (2)

Potential advantage: Salting and hashing does not allow for easily deducting hostnames from zone walks

Problem:

- □ Hostnames usually have very low entropy (to remember them)
- □ Easy dictionary attacks despite the usage of salts & iterations
- But not used heavily anyways:
 - .: Uses NSEC
 - .com: No salt, No iterations
 - .de: Static salt BA5EBA11, 15 Iterations
- Only solution generate NSEC3 records "on-demand"

□ For a question q generate NSEC3 answers for h(q) - 1 and h(q) + 1

- Slow (DoS) & Protection of keys?
- □ NSEC3 = Complicated mechanism for low gain...

Reconcernet DNSSEC Issues

Pro's:

DNSSEC allows to counter unauthorized/spoofed DNS records

- Con's:
 - □ Added complexity (signing, checking, key distribution)
 - Significant chance of misconfiguration
 - DoS attacks on DNS servers
 - Zones completely need to be signed otherwise no gain!
 - No confidentiality of requests/responses
 - Authenticated denial with NSEC and NSEC3 gives the possibility to "walk" and to gain knowledge on the full zone content (all zones/ sub domains) in O(N)
 - This may be a privacy violation due to some regulations...
 - Trust hierarchy without redundancy & anchor keys in the hand of single US company

Protection (SS 2023): 05 - Secure Name Resolution

39

Alternatives to DNSSEC*

- Some more or less exotic approaches
- "Transport Layer" Encryption
 DNSCurve
- Distributed Name Resolution
 - Peer Name Resolution Protocol
 - GNU Name System
- Try different strategies to deal with Zookos triangle, informally stating that global name resolution can only offer any two of the following properties:
 - □ Security
 - Distributed system
 - □ Human-memorable Names

DNSCurve (I)

TELEMATIK Rechnernetze

- Developed by Daniel Bernstein as an alternative to DNSSEC [Ber09]
- Uses online cryptographic functions, i.e., more like transport layer encryption
- □ Exchanges (either binary or tunneled in DNS TXT records):

$$C \to S: (+K_C, r_C, B[r_C, -K_C, +K_S, Request])$$

$$S \to C: (r_C, r_S, B[r_C || r_S, -K_S, +K_C, Reply]))$$

□ With B[] being the "cryptographic box function" developed by Bernstein

$$\begin{split} K_s &:= H(\{+K_2\}_{-K_1}, 0) = H(\{+K_1\}_{-K_2}, 0) \\ B[n, -K_1, +K_2, m] &:= H_2(\{m\}_{g(K_s, n)}) ||\{m\}_{f(K_s, n)} \end{split}$$

 Online operation possible using very efficient ciphers: Curve25519 (ECC based pub key system), Poly1305 (hash function) and Salsa20 (stream cipher) all developed by Bernstein

Protection (SS 2023): 05 - Secure Name Resolution

41

DNSCurve (II) – Distribution of public keys

- Public keys are not validated using novel records, but DNS names
- Name servers are no longer called ns.example.org but like uz5xgm1kx1zj8xsh51zp315k0rw23csgyabh2s17g8tjg25 ltcvhyw.example.org
 - □ uz5 means name server speaks DNSCurve
 - Rest of the string encodes 256 bit public key
- Parent zones pointing to DNSCurve names allow to verify sub zones
- □ DNSCurves in hyperlinks etc. allow to verify DNSCurve servers independent of DNS hierarchy! → No more trust in root zone...

DNSCurve (III) – Discussion

- Slimmer design compared to DNSSEC
- □ Independent trust paths possible
- Support for confidentiality
- No amplification attacks possible
- But use of hard defined cryptographic operations is not globally acceptable
- Cipher operations are not as well examined as ciphers in DNSSEC

43

Protection (SS 2023): 05 - Secure Name Resolution

Peer Name Resolution Protocol (PNRP) [Mic13]

- Distributed protocol invented by Microsoft based on Pastry
- Deployed with modern Windows systems, but disabled by default and requiring IPv6
- All computers are equal nodes in structured overlay networks (called clouds here)
 - □ Link cloud (for all local computers)
 - □ Site cloud (e.g. for all computers of a company)
 - Global cloud (for all PNRP speakers in the Internet)
- Names in the form name.pnrp.net can be resolved insecurely (pnrp.net being a special domain to map PNRP names in the DNS name space)
- Names in the form pnamep-authority.pnrp.net, with authority being a SHA-1 hash of a node's public key can be securely resolved

PNRP – Properties

Abandonment of servers might increase robustness and availability of overall system, but no wide research (yet)

□ Some mechanisms to prevent well known eclipse and sybil attacks

- Different clouds allow for increased performance and robustness within same network locations
- Secure names can be verified independently of a trust hierarchy
- Secure names cannot be remembered
- Secure names cannot be verified by a trust hierarchy
- □ In the insecure name space: anarchy!
 - No security guarantees at all
 - □ Anybody may register and reregister addresses...

Protection (SS 2023): 05 - Secure Name Resolution

GNU Name System (GNS) [EG11]

- Also distributed name resolution system based on GNUnet (spanning a Kademlia like structured peer-to-peer overlay)
- □ Also offers secure names in the form *hash.zkey*
- Again not memorable, but GNS offers aliases (so called *petnames*)
 - Every participant may create aliases like alias.gnu pointing to something.zkey
 - and aliases may be recursive (if users permit)... thus bob.alice.gnu points to a system that Alice (known by local system) calls bob
- □ Allows locally unambiguous names with a clear trust hierarchy
- Global names still possible by unmemorable names
